CounterFactual: pitch script (5 minutes, 11 slides)

Speakers: Jayen presents every slide. **Vakhtang** runs and narrates the live demo (slide 7) and drives the laptop.

Before you start: dashboard open in a second tab (accel-claims-dashboard.vercel.app), example 21 ready, terminal open with `python -m insurance.sim_link` already run.

Wording: say "recovery case" and "triage evidence". Never call a named company "liable" or "defective". Always quote careful drivers A and B together. Give ranges, never a single number.

---

1. Cover · Jayen · 0:00–0:15

> When a driverless car crashes, someone pays, and the insurer needs to know one thing fast: can we get that money back from the company behind the vehicle? We're CounterFactual. We give claims teams that answer in minutes, with the evidence behind it.

2. Why it is needed · Jayen · 0:15–0:45

> Driverless cars crash far less. One insurer study found 88% fewer property claims and 92% fewer injury claims than human drivers. So the claims that remain are few, contested and high-stakes.
>
> The proof sits with the other side: the driving logs belong to the operator.
>
> And recovery is real money. US insurers filed about 27 billion dollars of recovery demands last year, and recovery firms keep up to a third of it.
>
> Insurers make two costly mistakes: chasing a claim they'll lose, and missing one they'd win.

3. Target market · Jayen · 0:45–1:10

> We sell across the whole liability chain: fleet insurers and reinsurers, the robotaxi operators themselves for their defence, and the agents who place that cover.
>
> Honestly, driverless-only claims are a small market today, about 7.7 million dollars a year by 2030. That's why we also screen driver-assist claims, which are 15 to 20 times more common now.

4. Why start in the United States · Jayen · 1:10–1:40

> We start where the vehicles and the data are. Waymo runs about 500,000 paid rides a week, about 200 million driverless miles a year. Tesla's driver-assist system has logged 8 billion miles, on Tesla's own figures, which gives us volume to screen.
>
> The US also publishes crash reports, so we can test ourselves. Our simulator reproduces 88% of real crashes in a public study.
>
> The UK comes next, when its Automated Vehicles Act regime goes live, expected late 2027.

5. One claim, start to finish · Jayen · 1:40–2:15

> Here's what happens to a claim. The crash file comes in and we check it hasn't been tampered with. We work out who was in control. Then the simulator asks the key question: would a careful driver have avoided this? We run two published reference drivers, A and B.
>
> From that we price what's recoverable as a range, after legal costs. Every claim ends in one of eight outcomes with next steps and the deadline. Then a named person signs off.
>
> One rule matters most: code produces every number. The agents only challenge it.

6. The agent team · Jayen · 2:15–2:40

> Four agents work the queue for hours without supervision. A lead picks each claim and hands it to an investigator, a reconstructor and a counterfactual analyst.
>
> They're built for long runs: a budget cap, retry limits, and a full trace of every run. If the simulator can't reproduce a crash in five tries, the claim is flagged, not forced.

7. Cue the demo · Vakhtang · 2:40–4:00

(Jayen hands over: "Vakhtang will show you a live claim." Vakhtang switches to the dashboard.)

- **Inbox (15s):** "27 claims, each with a decision and a pound range."
- **One claim (25s):** open example 21. "Both careful drivers avoid this crash 99 to 100% of the time. Expected recovery is 8.9 to 51.2 thousand pounds, after legal cost. Outcome: pursue, with a letter before action."
- **Agent run (15s):** show the hand-offs and a retry in the trace.
- **Debate (25s):** "Before a human sees it, the system argues with itself. Defence counsel attacks the weakest assumption and the adjuster rebuts. If a rejected challenge would flip the decision, the claim goes to a human, marked contested."

(Vakhtang switches back to the slides and hands back: "Over to Jayen.")

8. Three ways to charge · Jayen · 4:00–4:20

> Three ways to charge. Per claim, 300 pounds. A 10% success fee, well under what recovery firms take. Or a 40 to 80 thousand pound subscription, which is the one that scales.
>
> The AI costs 27 cents a claim. Human review is most of the cost, and we keep it on purpose. Margins are around 87 to 90%.

9. Risks · Jayen · 4:20–4:45

> We'll name the risks before you do.
>
> • The market is small before 2030, so we start in the US and sell subscriptions.
>
> • Our engine models UK law today, so we're building the US model with counsel.
>
> • The operator holds the evidence, so we send a preservation letter, then a disclosure request.
>
> • The models are guidance, not law, so a human always signs off.
>
> • And this must never be used against a victim. Victims are paid first, and our output is triage, never a verdict.

10. Ready for real claims · Jayen · 4:45–5:00

> It works today: 22 crashes reproduced, the agents and a live dashboard, over 200 tests. What we need is a 2 million pound seed, one insurer or operator for a US pilot, and one US counsel.

11. Any questions? · Jayen (Vakhtang takes demo questions)

> Thank you. Happy to take questions.

Likely questions (one line each)

- **Is this legal today?** "We start in the US. The UK regime isn't live yet, and we flag that on every claim." (Jayen)
- **Why trust the number?** "It comes from published reference models, always shown as a range from drivers A and B, and a human signs off." (Jayen)
- **What if the operator won't share logs?** "A preservation letter, then a court disclosure request. We also show what better evidence would change." (Jayen)
- **How do you make money?** "Per claim, a success fee, or a subscription. The subscription is what scales." (Jayen)
- **What's real?** "22 example crashes reproduced, two agent systems, a live dashboard. The crash data is synthetic." (Vakhtang, who can show it)

If the demo fails

Stay on slide 7 and run the terminal proof: `python -m insurance insurance/examples/21_pursue_cut_in.json --price`. Then read the outcome, the range and the next steps aloud.
